CAS INDEXING IS AVAILABLE FOR THIS PATENT.
            . the unknown DNA sequence area and thereby copying the template
SUMM
       and synthesizing a complementary strand using DNA polymerases, such as
       Klenow fragment of E. coli DNA
       polymerase I, a DNA polymerase from Thermus
       aquaticus, Taq DNA polymerase, or a modified T7
       DNA polymerase, Sequenase (e.g., Tabor et al., (1987)
       Proc. Natl. Acad. Sci. U.S.A. 84:4767-4771), in the presence of
       chain-terminating reagents. Here, the. . . sequencing DNA require the
       use of polyacrylamide gel electrophoresis (i.e., PAGE) that can result
       in sequencing artifacts or require detectable labels, such as
       radioisotopes, enzymes, or fluorescent or chemiluminescent moieties.
SUMM
            . a further object herein to provide methods of sequencing
       nucleic acids in an array format using RNA polymerase in which
       nucleic acid probes are immobilized to supports at
       high densities to facilitate mass spectrometric detection. It is also an
       object herein to.
SUMM
       In certain embodiments, a double stranded nucleic acid
       molecule encoding a promoter sequence is isolated from a natural source
       (e.g., bacteria, viruses, bacteriophages, plants or eukaryotic
       organisms) or. . . of the coding strand. This single stranded region
       is designed such that it is complementary to a region of the
       nucleic acid to be sequenced or to a common
       overlapping sequence (e.g., a restriction endonuclease site). In
       preferred embodiments, the promoter-containing nucleic
       acid is covalently coupled via the 3'-end of the noncoding
       strand or 5'-end of the coding strand to a solid support.
SUMM
       The nucleic acid to be sequenced containing at least
```

a partially single stranded 3'-end is hybridized to the complementary

sequences of the promoter-containing DNA. The nucleic
acid to be sequenced may be single stranded or double stranded.
The hybridization of the two nucleic acid molecules
introduces one or more "nicks" in the hybrid at the junction(s) of the
adjacent nucleic acid molecules. In certain
embodiments, nicks in the coding or non-coding strand, preferably the
coding strand, are ligated by the addition of an appropriate
nucleic acid ligase prior to initiating transcription
(i.e., DNA or RNA ligase).
. . . is analyzed by matrix-assisted laser desorption/ionization mass
spectrometry (MALDI) and preferably further uses time-of-flight (TOF)
analysis. The sequence of the nucleic acid is
obtained by aligning the observed mass of the chain-terminated RNA
transcripts obtained from sequencing reactions containing each of the.

SUMM

SUMM

SUMM method of sequencing may be used for diagnostic applications to determine the presence of genetic alterations in a known target nucleic acid. For example, a region of the target nucleic acid is amplified and the nucleic acid strand corresponding to the noncoding strand is isolated. The nucleic acid probe containing the promoter may be isolated from a natural source or assembled synthetically by hybridizing two complementary oligonucleotides to. sequence. A single stranded region of at least 5 nucleotides that is complementary to a region of the nucleic acid to be sequenced or to a common sequence is introduced by recombinant means at the 3'-end of the coding strand. In preferred embodiments, the promoter-containing nucleic acid is covalently coupled via the 3'-end of the noncoding strand or 5'-end of the coding strand to a solid support.

A single stranded 3' overhang of the nucleic acid to be sequenced, in single stranded or double stranded form, is hybridized to the complementary sequences of the noncoding strand and, in some embodiments, the nick(s) between one or more nucleic acid strands is/are ligated prior to transcription.

Transcription is initiated using the appropriate RNA polymerase in the presence of ribonucleoside triphosphates. . .

When used in array formats, a panel of promoter-containing nucleic acid probes may be constructed such that the single stranded complementary regions of the target nucleic acid may be permuted along the entire sequence, e.g., the coding sequence of a gene, allowing for the determination of the nucleic acid sequence of the entire gene during a single reaction sequence.

SUMM . . . may be identified using mass spectrometric methods. In practicing the methods, a single stranded region of the 3'-end of the nucleic acid to be sequenced is hybridized to a complementary sequence at the 3'-end of the coding strand a promoter-containing nucleic acid probe. In preferred embodiments, the promoter-containing nucleic acid is covalently coupled via the 5'-end of the noncoding strand or 3'-end of the coding strand to a solid support. . .

strand may be ligated by the addition of an appropriate nucleic acid ligase prior to initiating transcription (i.e., adding a DNA or RNA ligase). The mass of the terminated RNA transcripts is.

DRWD . . . silicon dioxide was reacted with 3-minopropyltriethoxysilane to produce a uniform layer of primary amino groups on the surface. A heterobifunctional crosslinking agent was then reacted with the primary amine to incorporate an iodoacetamide-group. An oligodeoxynucleotide containing a 3'- or 5'-disulfide (shown as. . .

DETD As used herein, the term "nucleic acid" refers to oligonucleotides or polynucleotides such as deoxyribonucleic acid (DNA) and ribonucleic acid (RNA) as well as analogs of either RNA or DNA, for

example, made from nucleotide analogs, any of which are in single or double-stranded form. **Nucleic acid** molecules can be synthetic or can be isolated from a particular biological sample using any number of procedures which are. . .

- DETD As used herein, a nucleic acid promoter-containing probe refers to a nucleic acid fragment that includes a double-stranded region encoding a promoter and a single-stranded region that contains at least 5 nucleotides at. . . the coding strand relative to the promoter that is complementary to a single stranded region at the 3'-end of a nucleic acid to be sequenced.
- DETD As used herein, the target nucleic acid is the nucleic acid that is sequenced. The target nucleic acid will contain or will be modified to contain at least about 5 nucleotides whose sequence is known for hybridization to the immobilized nucleic acid promoter-containing probe.
- DETD As used herein, nucleic acid synthesis refers to any process by which oligonucleotides or polynucleotides are generated, including, but not limited to processes involving chemical. . .
- The term "cross-linking agent" is art-recognized, and, as used herein, refers to reagents which can immobilize a nucleic acid to an insoluble-support, preferably through covalent bonds. Thus, appropriate "cross-linking agents" for use herein includes a variety of agents that. . . with a functional group present on a surface of the insoluble support and with a functional group present in the nucleic acid molecule. Reagents capable of such reactivity include homo- and hetero-bifunctional reagents, many of which are known in the art. Heterobifunctional. . .
- DETD As used herein, the terms "protein", "polypeptide" and "peptide" are used interchangeably when referring to a translated nucleic acid (e.g. a gene product).
- DETD . . . transcription would have occurred if a wild-type or native promoter had been used by the RNA polymerase to transcribe the nucleic acid in vitro.
- DETD As used herein, a "promoter-containing nucleic acid" is a nucleic acid that contains a sequence of nucleotides that directs the site-specific binding of an RNA polymerase molecule to form an open. . .
- DETD As used herein, a "coding strand" refers to the nucleic acid strand of a promoter-containing nucleic acid that has the same polarity as a corresponding mRNA molecule initiated from that promoter.
- DETD . . . a material used in mass spectrometry that is a proton donating, UV absorbing material, usually organic acid, that forms crystalline matrix-nucleic acid structures that are readily ionizable during MALDI. An exemplary matrix material is a solution of 3-hydroxypicolinic acid (3-HPA, 0.7 M. . .
- Mass spectrometric methods of sequencing nucleic acids are provided. The sequencing methods use immobilized nucleic acid promoter-containing probes that contain a double stranded region encoding a promoter and a single stranded region for hybridizing target nucleic acids. The nucleic acid sequence is determined by generating a set of nested base-specific chain terminated RNA transcripts that are analyzed using mass spectrometry.
- DETD . . . the art: Qβ replicase (e.g., see U.S. Pat. No. 5,696,249, Re: 35,443 and Eoyang et al. (1971) in Procedures in **Nucleic**Acid Research, Cantoni and Davies, eds., Volume 2, pp. 829-839, Harper and Rowe, N.Y.); bacteria (e.g., E. coli, see Burgess and.
- DETD The selection of the appropriate RNA polymerase for any given nucleic acid template to be sequenced is within the skill of the skilled artisan and varies according to the nucleic acid molecule to be sequenced. The selection may be determined empirically following the teachings known to those of skill in the.

Each nucleic acid promoter-containing probe used in DETD the sequencing methods described herein contains a promoter. The promoters used in the methods herein may be obtained from any source, i.e., recombinant or naturally-occurring promoter elements, or may be assembled from synthetic nucleic acid oligonucleotide sequences. For example, the nucleic acid containing a promoter may be obtained directly from a variety of different organisms, such as bacteria, viruses and eukaryotic organisms,. . . bla or lac promoters, RSV-LTR promoter and F9-1 promoter; Stratagene). The selection of the appropriate promoter will depend on the nucleic acid to be sequenced, sequencing conditions, and most importantly, on the RNA polymerase selected for transcription. DETD Immobilization of Nucleic Acid Promoter-containing Probes In preferred embodiments, the nucleic acid DETD promoter-containing probe is immobilized, directly or by means of a cross-linking agent, to a solid support provided herein. Preferred solid. In embodiments of the methods in which a cross-linking reagent is not DETD employed, a modified nucleic acid is reacted directly with a appropriately functionalized surface to yield immobilized nucleic acid. Thus, for example, an iodoacetyl-modified surface (or other thiol-reactive surface functionality) can react with a thiol-modified nucleic acid to provide immobilized nucleic acids. DETD acids immobilized on the insoluble support. The cross-linking agent (and other reagents used to functionalize the support surface or the nucleic acid molecule) can be selected to provide any desired spacing of the immobilized nucleic acid molecules from the support surface, and to provide any desired spacing of the immobilized nucleic acids from each other. Thus, steric encumbrance of the nucleic acid molecules can be reduced or eliminated by choice of an appropriate cross-linking agent. In certain embodiments, the cross-linking reagent can. multiple nucleic acids to a single cross-linking moiety. Preferably, the cross-linking agent is selected to be highly reactive with the nucleic acid molecule, to provide rapid, complete, and/or selective reaction. In preferred embodiments, the reaction volume of the reagents (e.g., the thiol. DETD Modified Nucleic Acid Promoter-containing Probes and Linkers DETD Preferred nucleic acid promoter-containing probes for use herein are "thiol-modified nucleic acids," i.e., nucleic acids derivatized to contain at least one reactive thiol. . . detail in Example 1, below, nucleic acids containing at least one reactive thiol are preferably made by treating a nucleic

Preferred nucleic acid promoter-containing probes
for use herein are "thiol-modified nucleic acids," i.e., nucleic acids
derivatized to contain at least one reactive thiol. . . further
detail in Example 1, below, nucleic acids containing at least one
reactive thiol are preferably made by treating a nucleic
acid containing a 3' or 5' disulfide with a reducing agent,
which preferably will not compete in subsequent reactions (i.e. will.
. react with an iodoacetimido functionality). Disulfide-derivatized
nucleic acids can be synthesized according to a variety of methods. For
example, a nucleic acid can be modified at the 3'or 5'-terminus by reaction with a disulfide-containing modifying a
reagent. Alternatively, a thiolated primer can by enzymatically or
non-enzymatically attached to the nucleic acid. A
5'-phosphoramidate functionality can also provide an attachment point
for a thiol or disulfide-containing cytosine or deoxycytosine. Examples
of reducing agents appropriate for reduction of a disulfide-modified
nucleic acid include: tris-(2-carboxyethyl)phosphine
(TCEP) (preferably a concentration in the range of 1-100 mM (most
preferably about 10 mM)) is reacted at. .

DETD In other embodiments, the nucleic acid is immobilized using the photocleavable linker moiety that is cleaved

during mass spectrometry. Exemplary photolabile cross-linker include, but are not. . .

- DETD A nucleic acid promoter-containing probe can be directly linked to a solid support via a reversible or irreversible bond between an appropriate functionality (L') on the target nucleic acid molecule (T) and an appropriate functionality (L) on the capture molecule. A reversible linkage can be such that it is. . .
- DETD . . . ammonium group, in which case, preferably, the surface of the solid support carries negative charges which repel the negatively charged nucleic acid backbone and thus facilitate the desorption required for analysis by a mass spectrometer. Desorption can occur either by the heat. . .
- DETD . . . can serve this purpose and that the donor functionality can be either on the solid support or coupled to the **nucleic**acid molecule to be detected or vice versa.
- DETD As noted, at least three version of immobilization are contemplated herein: 1) the target nucleic acid is amplified or obtained (the target sequence or surrounding DNA sequence must be known to make primers to amplify or isolated); 2) the primer nucleic acid is immobilized to the solid support and the target nucleic acid is hybridized thereto to form a promoter sequence; or 3) a double stranded nucleic acid encoding a promoter (amplified or isolated) is immobilized through linkage to one predetermined strand, and in vitro transcription is initiated. . .
- DETD In the embodiments where the primer nucleic acid is immobilized on the solid support and the target nucleic acid is hybridized thereto, the inclusion of the cleavable linker allows the primer DNA to be immobilized at the 5'-end so.
- DETD . . . those of skill in the art for immobilizing nucleic acids to solid supports may be used herein to link the nucleic acid to a solid support. The preferred linkers herein are the selectively cleavable linkers, particularly those exemplified herein. Other linkers include, . . .
- DETD . . . cross linking reagents that produce photocleavable linkages), thereby releasing the targeted agent upon exposure to light. In preferred embodiments, the nucleic acid is immobilized using the photocleavable linker moiety that is cleaved during mass spectrometry.
- DETD A variety of chemically cleavable linkers may be used to introduce a cleavable bond between the immobilized nucleic acid and the solid support. Acid-labile linkers are presently preferred chemically cleavable linkers for mass spectrometry, especially MALDI-TOF MS, because the acid labile bond is cleaved during conditioning of the nucleic acid upon addition of the 3-HPA matrix solution. The acid labile bond can be introduced as a separate linker group, e.g., the acid labile trityl groups or may be incorporated in a synthetic nucleic acid linker by introducing one or more silyl internucleoside bridges using diisopropylsilyl, thereby forming diisopropylsilyl-linked oligonucleotide analogs. The diisopropylsilyl bridge replaces. . .
- DETD . . . sugar moiety of a nucleotide at positions other than the 3' and 5' position is possible through conventional methods. Also, nucleic acid bases can be modified, e.g., as described in F. Eckstein, ed., "Oligonucleotides and Analogues: A Practical Approach," IRL Press (1991).. . .
- In preferred embodiments, modification of a nucleic acid, e.g., as described above, does not substantially impair the ability of the nucleic acid or nucleic sequence to hybridize to its complement. Thus, any modification should preferably avoid substantially modifying the functionalities of the nucleic acid which are responsible for Watson-Crick base pairing. The nucleic acid can be modified such that a non-terminal thiol group is present, and the nucleic acid, when

```
immobilized to the support, is capable of self-complementary base
       pairing to form a "hairpin" structure having a duplex region.
            . rate enzyme turnover. For example, the addition of 4-thio UTP,
DETD
       5-bromo UTP, 5-iodo CTP alter the hydrogen bonding of the
       nucleic acid facilitating, at least with some RNA
       polymerases, transcriptional termination and transcript release.
DETD
       In preferred embodiments, nucleic acid
       promoter-containing probes are immobilized at high densities to the
       surface of a solid support in an array format. Particularly suitable.
DETD
       In one preferred embodiment, a double stranded nucleic
       acid sequence encoding a promoter sequence is isolated from a
       natural source e.g., bacteria, viruses, bacteriophages, plants or
       eukaryotic organisms) or. . . Laboratory Press, New York). This
       single stranded region is designed such that it is complementary to a
       region of the nucleic acid to be sequenced or to an
       sequence shared between the two nucleic acid
       molecules (e.g., restriction endonuclease site).
DETD
       The nucleic acid to be sequenced containing at least
       a partially single stranded 3'-end is hybridized according to the
       conditions described herein and known to those of skill in the art to
       the complementary sequences of the promoter-containing DNA. The
       nucleic acid to be sequenced may be single stranded or
       double stranded. The hybridization of the two nucleic
       acid molecules introduces one or more "nick" in the hybrid at
       the junction(s) of the adjacent nucleic acid
       molecules. Nicks in the coding or non-coding strand, preferably the
       coding strand, can be ligated by the addition of an appropriate
       nucleic acid ligase prior to initiating transcription.
       Methods for ligating nucleic acids are well known to those of skill in
       the art.
DETD
            . method of sequencing may be used for diagnostic applications to
       determined the presence of genetic alterations in a known target
       nucleic acid. For example, a region of the target
       nucleic acid can be amplified using standard methods,
       such as PCR or other amplification methods known to those of skill in
               . art (e.g., see Sambrook et al., (1989) Molecular Cloning,
       2nd ed., Cold Spring Harbor Laboratory Press, New York). The amplified
       nucleic acid can be denaturated and the strand to be
       sequenced, i.e., the noncoding strand, is isolated or may be used as.
DETD
       In preferred embodiments, the nucleic acid
       promoter-containing probe is covalently immobilized on a silica support
       by functionalization of the support with an amino functionality (e.g.,
           . . (Pierce, Rockford, Ill.). Other homo- and hetero-bifunctional
       reagents which can be employed are available commercially, e.g., from
       Pierce. Finally, a nucleic acid functionalized with
       a thiol group (e.g., at the 5'-terminus) is covalently bound to the
       derivatived silica support by reaction of the thiol functionality of the
       nucleic acid molecule with the iodoacetyl
       functionality of the support.
DETD
       In certain embodiments, the nucleic acid can be
       reacted with the cross-linking reagent to form a cross-linker/
       nucleic acid conjugate, which is then reacted with a
       functionalized support to provide an immobilized nucleic
       acid. Alternatively, the cross-linker can be combined with the
       nucleic acid and a functionalized solid support in one
       pot to provide substantially simultaneous reaction of the cross-linking
       reagent with the nucleic acid and the solid support.
       In this embodiment, it will generally be necessary to use a
       heterobifunctional cross-linker, i.e., a cross-linker with two different
       reactive functionalities capable of selective reaction with each of the
      nucleic acid and the functionalized solid support.
DETD
              insoluble support can be selectively cleaved (e.g., by
```

```
photolithography) to provide portions of a surface activated for
immobilization of a nucleic acid. For example, a
silicon surface, modified by treatment with 3-mercaptopropyl-
triethoxysilane to provide thiol groups, can be blocked with a
photocleavable.
                 . . and be selectively deblocked by irradiation of
selected areas of the surface, e.g., by use of a photolithography mask.
A nucleic acid promoter-containing probe modified to
contain a thiol-reactive group can then be attached directly to the
support, or, alternatively, a thiol-reactive cross-linking reagent can
be reacted with the thiol-modified support, followed by (or
substantially simultaneously with) reaction with a nucleic
acid to provide immobilized nucleic acids. A nucleic
acid base or sequence, once immobilized on a support according
to the methods described herein, can be further modified according to
known methods. for example, the nucleic acid
sequence can be lengthened by performing solid-phase nucleic
acid synthesis according to conventional techniques, including
combinatorial technique.
      . may be identified using mass spectrometric methods. In
practicing the methods, a single stranded region of the 3'-end of the
nucleic acid to be sequenced is hybridized to a
complementary sequence at the 3'-end of the coding strand a
promoter-containing nucleic acid probe. In preferred
embodiments, the promoter-containing nucleic acid is
covalently coupled via the 5'-end of the noncoding strand or 3'-end of
the coding strand to a solid support.
In certain embodiments, nicks in one or more strand resulting from the
hybridization of the nucleic acid to be sequenced
may be ligated by the addition of an appropriate nucleic
acid ligase prior to initiating transcription (i.e., adding a
DNA or RNA ligase).
        hybridized, radiolabeled probes were employed. In cases where a
5'-disulfide-containing oligodeoxynucleotide was to be immobilized, the
3'-terminus was radiolabeled using terminal
transferase enzyme and a radiolabeled dideoxynucleoside
triphosphate; in a standard reaction, 15 pmol (0.6 \mu M) of the
5'-disulfide-containing oligodeoxynucleotide was incubated.
Use of High Density Nucleic Acid Immobilization to
Generate Nucleic Acid Arrays
All primers were synthesized on a commercially available DNA Synthesizer
using conventional phosphoroamidite chemistry (Sinha et al. (1984)
Nucleic Acid Res. 12:4539). In vitro RNA transcription
was performed on a synthetic 55 nucleotide double stranded DNA template.
The template was.
All primers were synthesized on a commercially available DNA Synthesizer
using conventional phosphoroamidite chemistry (Sinha et al. (1984)
Nucleic Acid Res. 12:4539). In vitro RNA transcription
was performed on a synthetic 276 nucleotide double stranded DNA template
(SEQ ID No..
What is claimed is:
1. A method for determining the sequence of a target nucleic
acid molecule, comprising: a) immobilizing a nucleic
acid promoter-containing probe on a solid support, wherein: the
nucleic acid promoter-containing probe comprises at
least 5 nucleotides at the 3'-end of the coding strand that is
complementary to a single stranded region at the 3'-end of the target
nucleic acid, and a double-stranded portion that
comprises the promoter, which is oriented to permit transcription of a
hybridized target nucleic acid molecule; b)
hybridizing the target nucleic acid to the
single-stranded portion of the immobilized nucleic
acid probe; c) transcribing the target nucleic
acid with an RNA polymerase to produce a plurality of
base-specifically terminated RNA transcripts, wherein the RNA polymerase
```

recognizes the promoter;. . . the molecular weight value of each base-specifically terminated RNA transcript by mass spectrometry; and e) determining the sequence of the **nucleic acid** by aligning the base-specifically terminated RNA transcripts according to molecular weight.

- 3. The method of claim 1, wherein the immobilized **nucleic acid** promoter-containing probe is produced by immobilizing a single-stranded molecule that comprises a promoter or the complement of a promoter and. . .
- . to form a phosphodiester bond between the 3' hydroxyl group and the 5' phosphate group of adjacent strands of the nucleic acid probe and the target nucleic acid.
- 10. The method of claim 1, wherein prior to immobilization of the nucleic acid, the surface of the support is derivatized by reacting the surface with an aminosilane to produce primary amines on the. . .
- 14. The method of claim 12, wherein the immobilization of the nucleic acid probe to a solid support is effected by reacting the thiol-reactive solid support with a nucleic acid probe having a free 5'- or 3'-thiol group, whereby a covalent bond between the thiol group and the thiol-reactive solid.
- 15. The method of claim 1, wherein the **nucleic acid** probe is covalently bound to a surface the solid support at a density of at least 20 fmol/mm.sup.2.
- 18. The method of claim 1, wherein the surface comprises a plurality of wells comprising the immobilized **nucleic acid** molecule.
- 25. The method of claim 1, wherein the hybridization of the **nucleic acid** to be sequence to the solid support results in the formation of a nick in the coding strand corresponding to. . .
- 28. A method of identifying transcriptional terminator sequences or attenuator sequences in a target nucleic acid molecule, comprising: a) immobilizing a nucleic acid promoter-containing probe on a solid support, wherein the nucleic acid promoter-containing probe comprises at least 5 nucleotides at the 3'-end of the coding strand that is complementary to a single stranded region at the 3'-end of the target nucleic acid, and a double-stranded portion that comprises the promoter, which is oriented to permit transcription of a hybridized target nucleic acid molecule; b) hybridizing the target nucleic acid molecule to the immobilized nucleic acid probe; c) transcribing the target nucleic acid with an RNA polymerase to produce a sequence-terminated RNA transcript, wherein the RNA polymerase recognizes the promoter; and d) determining. . . observed mass of the RNA is indicative of the presence of a the terminator sequence or attenuator in the target nucleic acid molecule.

CAS INDEXING IS AVAILABLE FOR THIS PATENT.
SUMM
               thus interfere with the replication or transcription of
       selected target genes. As is known, except for certain RNA viruses and
       nucleic acid-free viroids, DNA is the repository for
       all genetic information, including regulatory control sequences and
       non-expressed genes, such as dormant proviral.
SUMM
            . to inhibit restriction and/or transcription of the target
       double stranded DNA. Based on the known stabilities of the two target
       nucleic acid species (i.e., DNA and RNA), anti-gene
       interference with DNA functioning has longer lasting effects than the
       corresponding antisense inhibition of.
SUMM
            . chain of nucleotides which are linked to one another by
       phosphate ester linkages. Each nucleotide typically comprises a
       heterocyclic base (nucleic acid base), a sugar
       moiety attached to the heterocyclic base, and a phosphate moiety which
       esterifies a hydroxyl function of the.
SUMM
             . sugars or sugar analogs and of the respective "nucleosides"
       wherein such sugars or analogs are attached to a heterocyclic base (
       nucleic acid base) per se is known, and need not be
       described here, except to the extent such preparation is provided here.
SUMM
       The heterocyclic bases, or nucleic acid bases which
       are incorporated in the modified ODNs of the present invention may be
       the naturally occurring principal purine and.
SUMM
       Other examples of nucleotides where the crosslinking
       agent is attached to a heterocyclic base, are
       2'-deoxy-4-aminopyrazolo[3,4-d]pyrimidine derivatives. The general
       structure of these derivatives is shown below in Formula.
SUMM
                include ligands which bind to antibodies labeled with
       fluorophores, chemiluminescent agents, and enzymes. Alternatively,
       probes can be conjugated directly with labels such as
       fluorophores, chemiluminescent agents, enzymes and enzyme substrates.
       Alternatively, the same components may be indirectly bonded through a
       ligand-antiligand.
SUMM
               for example, by using DNA synthesizers, by nick-translation, by
```

```
tailing of radioactive bases in the 3' end of probes with
       terminal transferase, by copying M13 plasmids having
       specific inserts with the Klenow fragment of
       DNA polymerase in the presence of radioactive dNTP's,
       or by transcribing RNA from templates using RNA polymerase in the
       presence of radioactive.
SUMM
       The particular hybridization technique is not essential to the
       invention. Hybridization techniques are generally described in "
       Nucleic Acid Hybridization, A Practical Approach",
       Hames and Higgins, Eds., IRL Press, 1985; Gall and Pardue, Proc. Natl.
       Acad. Sci., U.S.A., 63:378-383.
SUMM
              present in the hybridization solution may vary widely.
       Generally, substantial excess of probe over the stoichiometric amount of
       the target nucleic acid will be employed to enhance
       the rate of binding of the probe to the target DNA or RNA.
       This first aspect of the invention is also directed to a method or
SUMM
       identifying target single stranded nucleic acid
       sequences, which method comprises utilizing an oligonucleotide probe
       including at least one ODN having a cross-linking agent and a label.
             . one labeled ODN having a cross-linker covalently attached,
SUMM
       wherein the ODN comprises a sequence complementary to that of the target
       nucleic acid sequence;
SUMM
       An assay for identifying target single stranded nucleic
       acid sequences utilizing a labeled oligonucleotide probe
       including the covalently attached cross-linking agent and comprising the
       above method is contemplated for.
                                          . . probe reagent (ODN) having a
       sequence complementary to that of the target nucleic acids; a
       denaturation reagent for converting double-stranded nucleic
       acid to a single-stranded nucleic acid; and
       a hybridization reaction mixture. The kit can also include a
       signal-generating system, such as an enzyme for example, and.
       DNA polymerase 1 (U.S. Biochemicals) -- 8 U/mL
DETD
DETD
          . . mL), nucleotide mix A (6 mL), Bio-12-dAPPTP (2 mL), and H.sub.2
       O (20 mL) was added DNase (1 mL) and DNA polymerase
       1 (2.4 mL). The reaction mixture was incubated at 16° C. for 1
       hour. The procedure was repeated using Bio-11dUTP.
       Nucleic acid was isolated by ethanol precipitation
DETD
       and hybridized to pHPV-16 slotted onto nitrocellulose. The hybridized
       biotinylated probe was visualized by a.
DETD
       The reaction of crosslinking a DNA probe to a target nucleic
       acid sequence contained 1 \mu g of haloacylamidoalkyl probe and
       10 ng of .sup.32 P-labeled cordycepin-tailed target in 200 \mu L of
DETD
                with the HPV system of Example 25 where U is
       5-(3-iodoacetamidoprop-1-yl)-2'-deoxyuridine. The target was .sup.32
       P-labeled by cordycepin tailing with terminal
       transferase (Maniatis et al., "Molecular Cloning -- A Laboratory
       Manual", Cold Spring Harbor Laboratory, 1982, p. 239) and incubated with
       excess probe in.
DETD
               the sugar or any heterocyclic base within the ODN. A
       cross-linking agent which has two cross-linking functionalities, such as
       a crosslinking agent having the formula
       --N--[(CH.sub.2).sub.2 --L].sub.2 (a bifunctional N-mustard) is capable
       of two alkylations, and is therefore considered as two cross-linking.

DETD
            . A 1 \mumol silica gel support column with the 3' base of the
       ODN (i.e. unmodified nucleotide, C-5-propyne nucleotide, or
      morpholino nucleotide analog) linked by the 3' hydroxy
       group is inserted, and synthesis is carried out in a base by base
       fashion. .
